

# The Pollination Process

# The Pollination Process Answers

## Step 1

The flower petal's bright colours and fragrant scents attract insects.

## Step 2

The insect arrives on the flower to collect nectar (sweet liquid). As it collects nectar, it rubs against the anthers, which rub pollen onto the insect.

## Step 3

The insect travels to a new flower, with pollen attached to its body.

## Step 4

As the insect feeds on the nectar of this other flower, the pollen on its body rubs off onto the female parts (stigma).

## Step 5

Some of the pollen travels down the style and into the ovary, where it will join with an ovule (meaning the plant has been fertilised).

## Step 6

The fertilised ovule will turn into a seed which will be dispersed to continue the lifecycle of this plant elsewhere.
